

Assumptions:

- Program Input assumptions:
 - The program assumes that all inputs provided by the user are in the correct format (e.g., numeric values for amount and currency choice).
 - The program assumes that any necessary validation checks will ensure that inputs are within the correct range (e.g., amount within currency limitations). Invalid inputs will trigger an error message and ask the user to input again.
 - It is assumed that the user will input only one amount at a time and not provide multiple amounts simultaneously.
 - As the user enters data, the program assume that they can understand and stick to the instructions given on the screen.
- Program Processing assumptions:
 - The program assumes that any necessary validation checks will ensure that inputs are within the correct range (e.g., amount within currency limitations). Invalid inputs will trigger an error message and ask the user to input again.
 - The program assumes that input errors such as non-numeric values or invalid amounts are handled through error-checking functions, ensuring the program doesn't crash unexpectedly.
- Program Output assumptions:
 - The program assumes that the output will be displayed promptly after processing, with no significant delay between input and output.
 - The program assumes that the output will be structured clearly and concisely, displaying the number of coins for each denomination.
 - The program assumes that all outputs, whether they are coin breakdowns or error messages, will follow a consistent format for ease of understanding and readability.
- Any other assumptions:
 - Assumes that the 'printf' and 'scanf' standard input/output functions from the C standard library operate error-free and as intended.
 - The program assumes that the user will follow the instructions correctly when asked if they want to continue or exit, providing 'y' or 'n' as the input.
 - The program assumes that the denominations for each currency will remain unchanged, and no updates to the coin values are needed.
